

PTPN11 — transcript structure and translated protein product

Rattus Norvegicus · 2 annotated transcript(s) · primary NM_001177593.1 -> NP_001171064.1 · 597 aa · transcribed left to right on the plus strand · panel A in nucleotides, panel B in amino acids

A Which coding exons does each transcript use, and which part of each translated protein do they encode? Exon identity in panel B is compared on genomic CDS coordinates; differences are descriptive annotation differences, not validated splicing events.

B coding exon of the primary transcript — intron / transcription direction

coding exon of the primary model shifted exon boundary (same exon, different CDS end)
shared genomic exon (identical CDS interval)
